Quantum bits (qubits) and quantum circuits

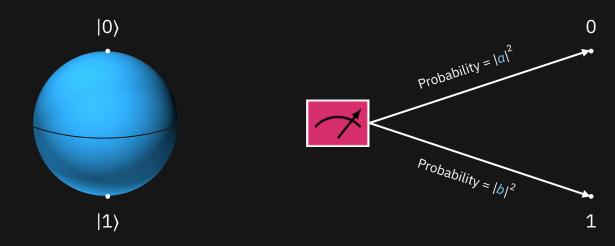

A quantum bit or qubit is a controllable quantum object that is the unit of information

A quantum circuit is a set of quantum gate operations on qubits and is the unit of computation

Bits and qubits

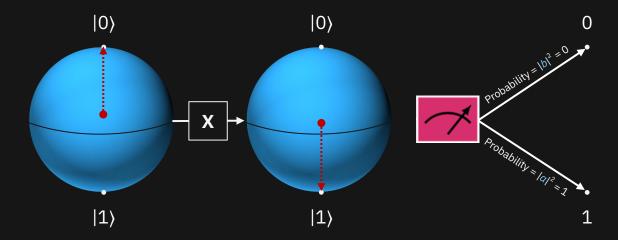

A qubit's state is a combination of $|0\rangle$ and $|1\rangle$:

$$a |0\rangle + b |1\rangle$$

This means that a single qubit contains two pieces of information.

When we measure a qubit, it becomes **0** or **1** based on probability.

The **X** gate reverses $|0\rangle$ and $|1\rangle$:

$$a \mid 0 \rangle + b \mid 1 \rangle \mapsto b \mid 0 \rangle + a \mid 1 \rangle$$

a = 1 and b = 0, so $|0\rangle$ is mapped to $|1\rangle$.

When measured, the result is **1** with 100% probability.

Superposition

 $|0\rangle$ and $|1\rangle$ are vectors in the two-dimensional complex vector space ${\bf C}^2$:

$$|0\rangle = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$
 and $|1\rangle = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$

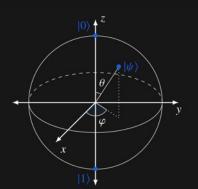

So we can write any vector in \mathbf{C}^2 as

$$a |0\rangle + b |1\rangle$$

We pronounce |0| and |1| as "ket zero" and "ket one." These are called the computational basis.

Superposition is creating a quantum state that is a combination of $|0\rangle$ and $|1\rangle$ $\alpha |0\rangle + b |1\rangle$

Superposition

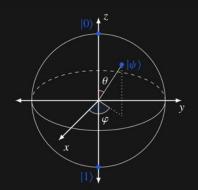

These conditions allow us to map the qubit onto the *Bloch Sphere*.

Note that if a and b are non-zero, then the qubit's state contains both $|0\rangle$ and $|1\rangle$.

This is what people mean when they say that a qubit can be "0 and 1 at the same time."

Measurement

Measurement is forcing the qubit's state

$$a |0\rangle + b |1\rangle$$

to $|0\rangle$ or $|1\rangle$ by observing it, where

 $|\alpha|^2$ is the probability we will get $|0\rangle$ when we measure

 $|b|^2$ is the probability we will get $|1\rangle$ when we measure

For example,

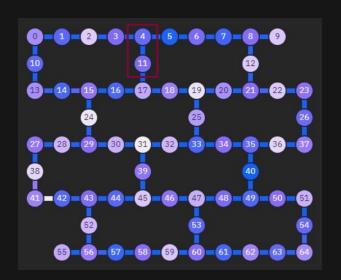

$$\frac{\sqrt{2}}{2}|0\rangle + \frac{\sqrt{2}}{2}|1\rangle$$

has an equal probability of becoming $|0\rangle$ or $|1\rangle$, and

$$\frac{\sqrt{3}}{2}|0\rangle - \frac{1}{2}i|1\rangle$$

has a 75% chance of becoming |0).

Entanglement

With two qubits we get combinations like

$$a \mid 00 \rangle + b \mid 01 \rangle + c \mid 10 \rangle + d \mid 11 \rangle$$

where

 $|01\rangle$ means the first qubit is $|0\rangle$ and the second is $|1\rangle$

a, b, c, and d are complex numbers and

$$|a|^2 + |b|^2 + |c|^2 + |d|^2 = 1$$

If two or more of the *a*, *b*, *c*, and *d* are non-zero, and we cannot separate the qubits, they are entangled with perfect correlation and are no longer independent.

Entanglement

For example,

$$\frac{\sqrt{2}}{2}|00\rangle + \frac{\sqrt{2}}{2}|01\rangle$$

not entangled

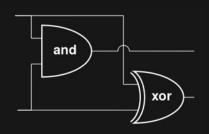

$$\frac{\sqrt{2}}{2}|01\rangle - \frac{\sqrt{2}}{2}|10\rangle$$

entangled

$$\frac{\sqrt{2}}{2}|00\rangle + \frac{\sqrt{2}}{2}|11\rangle$$

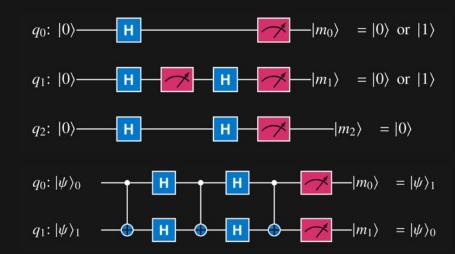

entangled

Gates / operations

Classical logical circuits use operations like and, or, not, nand, and xor. We also call these gates.

Quantum circuits use reversible gates that change the quantum states of one, two, or more qubits.

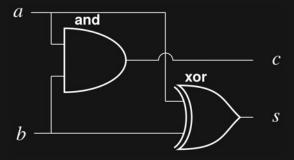

Bits and classical logic circuits
